

Class 11 Maths Chapter 15. Statistics

Statistics is the Science of collection, organization, presentation, analysis and interpretation of the numerical data.

Useful Terms

1. Limit of the Class

The starting and end values of each class are called Lower and Upper limit.

2. Class Interval

The difference between upper and lower boundary of a class is called class interval or size of the class.

3. Primary and Secondary Data

The data collected by the investigator himself is known as the primary data, while the data collected by a person, other than the investigator is known as the secondary data.

4. Variable or Variate

A characteristics that varies in magnitude from observation to observation. e.g., weight, height, income, age, etc, are variables.

5. Frequency

The number of times an observation occurs in the given data, is called the frequency of the observation.

6. Discrete Frequency Distribution

A frequency distribution is called a discrete frequency distribution, if data are presented in such a way that exact measurements of the units are clearly shown.

7. Continuous Frequency Distribution

A frequency distribution in which data are arranged in classes groups which are not exactly measurable.

Cumulative Frequency Distribution

Suppose the frequencies are grouped frequencies or class frequencies. If however, the frequency of the first class is added to that of the second and this sum is added to that of the third and so on, then the frequencies, so obtained are known as cumulative frequencies (cf).

Graphical Representation of Frequency Distributions

(i) **Histogram** To draw the histogram of a given continuous frequency distribution, we first mark off all the class intervals along X-axis on a suitable scale. On each of these class intervals on the horizontal axis, we erect (vertical) a rectangle whose height is proportional to the frequency of that particular class, so that the area of the rectangle is proportional to the frequency of the class.

If however the classes are of unequal width, then the height of the rectangles will be proportional to the ratio of the frequencies to the width of the classes.

(ii) **Bar Diagrams** In bar diagrams, only the length of the bars are taken into consideration. To draw a bar diagram, we first mark equal lengths for the different classes on the axis, i.e., X-axis.

On each of these lengths on the horizontal axis, we erect (vertical) a rectangle whose heights is proportional to **the frequency** of the class.

(iii) **Pie Diagrams** Pie diagrams are used to represent a relative frequency distribution. A pie diagram consists of a circle divided into as many sectors as there are classes in a frequency distribution.

The area of each sector is proportional to the relative frequency of the class. Now, we make angles at the centre proportional to the relative frequencies.

And in order to get the angles of the desired sectors, we divide 360° in the proportion of the various relative frequencies. That is,

$$\text{Central angle} = [\text{Frequency} \times 360^\circ / \text{Total frequency}]$$

(iv) **Frequency Polygon** To draw the frequency polygon of an ungrouped frequency distribution, we plot the points with abscissae as the variate values and the ordinate as the corresponding frequencies. These plotted points are joined by straight lines to obtain the frequency polygon.

(v) **Cumulative Frequency Curve (Ogive)** Ogive is the graphical representation of the cumulative frequency distribution. There are two methods of constructing an Ogive, viz (i) the 'less than' method (ii) the 'more than' method.

Measures of Central Tendency

Generally, average value of a distribution in the middle part of the distribution, such type of values are known as measures of central tendency.

The following are the five measures of central tendency

1. Arithmetic Mean
2. Geometric Mean
3. Harmonic Mean
4. Median
5. Mode

Arithmetic Mean

The arithmetic mean is the amount secured by dividing the sum of values of the items in a series by the number.

1. Arithmetic Mean for Unclassified Data

If n numbers, $x_1, x_2, x_3, \dots, x_n$, then their arithmetic mean

$$A \text{ or } \bar{x} = \frac{x_1 + x_2 + \dots + x_n}{n} = \frac{\sum x_i}{n}$$

2. Arithmetic Mean for Frequency Distribution

Let f_1, f_2, f_n be corresponding frequencies of x_1, x_2, \dots, x_n . Then,

$$A = \frac{x_1 f_1 + x_2 f_2 + \dots + x_n f_n}{f_1 + f_2 + \dots + f_n} = \frac{\sum x_i f_i}{\sum f_i}$$

3. Arithmetic Mean for Classified Data

Class mark of the class interval $a-b$, then $x = a + b / 2$

For a classified data, we take the class marks x_1, x_2, \dots, x_n of the classes as variables, then arithmetic mean

$$A = \frac{\sum xf}{\sum f} = \frac{\sum \frac{1}{2}(a_i + b_i) \times f_i}{\sum f_i}$$

Step Deviation Method

$$A = A_1 + \left(\frac{\sum f_i u_i}{\sum f_i} \right) h$$

where, A_1 = assumed mean

$$u_i = x_i - A_1 / h$$

f_i = frequency

h = width of interval

4. Combined Mean

If x_1, x_2, \dots, x_r be r groups of observations, then arithmetic mean of the combined group x is called the combined mean of the observation

$$A = n_1 A_1 + n_2 A_2 + \dots + n_r A_r / n_1 + n_2 + \dots + n_r$$

A_r = AM of collection x_r

n_r = total frequency of the collection x_r

5. Weighted Arithmetic Mean

If w be the weight of the variable x , then the weighted AM

$$A_w = \sum wx / \sum w$$

Shortcut Method

$$A_w = A_w' + \sum wd / \sum w, A_w' = \text{assumed mean}$$

$\sum wd$ = sum of products of the deviations and weight

Properties of Arithmetic Mean

- (i) Mean is dependent of change of origin and change of scale.
- (ii) Algebraic sum of the deviations of a set of values from their arithmetic mean is zero.

(iii) The sum of the squares of the deviations of a set of values is minimum when taken about mean.

Geometric Mean

If x_1, x_2, \dots, x_n be n values of the variable, then

$$G = \sqrt[n]{x_1, x_2, \dots, x_n}$$

or $G = \text{antilog} [\log x_1 + \log x_2 + \dots + \log x_n / n]$

For Frequency Distribution

$$G = (x_1^{f_1} x_2^{f_2} \dots x_n^{f_n})^{\frac{1}{N}}, \text{ where } N = \sum_{i=1}^n f_i$$

or
$$G = \text{antilog} \left[\frac{1}{N} (f_1 \log x_1 + f_2 \log x_2 + \dots + f_n \log x_n) \right]$$

Harmonic Mean (HM)

The harmonic mean of n items x_1, x_2, \dots, x_n is defined as

$$HM = \frac{n}{\frac{1}{x_1} + \frac{1}{x_2} + \dots + \frac{1}{x_n}} = \frac{n}{\sum_{i=1}^n \frac{1}{x_i}}$$

If their corresponding frequencies f_1, f_2, \dots, f_n respectively, then

$$HM = \frac{f_1 + f_2 + \dots + f_n}{\left(\frac{f_1}{x_1} + \frac{f_2}{x_2} + \frac{f_n}{x_n} \right)} = \frac{\sum_{i=1}^n f_i}{\sum_{i=1}^n \frac{f_i}{x_i}}$$

Median

The median of a distribution is the value of the middle variable when the variables are arranged in ascending or descending order.

Median (M_d) is an average of position of the numbers.

1. Median for Simple Distribution

Firstly, arrange the terms in ascending or descending order and then find the number of terms n .

(a) If n is odd, then $(n + 1 / 2)$ th term is the median.

(b) If n is even, then there are two middle terms namely $(n / 2)$ th and $(n / 2 + 1)$ th terms. Hence,

Median = Mean of $(n / 2)$ th and $(n / 2 + 1)$ th terms.

2. Median for Unclassified Frequency Distribution

(i) First find $N / 2$, where $N = \Sigma f_i$.

(ii) Find the cumulative frequency of each value of the variable and take value of the variable which is equal to or just greater than $N / 2$

(iii) This value of the variable is the median.

3. Median for Classified Data (Median Class)

If in a continuous distribution, the total frequency be N , then the class whose cumulative frequency is either equal to $N / 2$ or is just greater than $N / 2$ is called median class.

For a continuous distribution, median

$$M_d = l + ((N / 2 - C) / f) * h$$

where, l = lower limit of the median class

f = frequency of the median class

N = total frequency = Σf

C = cumulative frequency of the class just before the median class

h = length of the median class

Quartiles

The median divides the distribution in two equal parts. The distribution can similarly be divided in more equal parts (four, five, six etc.). Quartiles for a continuous distribution is given by

$$Q_1 = l + ((N / 4 - C) / f) * h$$

Where, N = total frequency

l = lower limit of the first quartile class

f = frequency of the first quartile class

C = the cumulative frequency corresponding to the class just before the first quartile class

h = the length of the first quartile class

Similarly, $Q_3 = l + ((3N / 4 - C) / f) * h$

where symbols have the same meaning as above only taking third quartile in place of first quartile.

Mode

The mode (M_0) of a distribution is the value at the point about which the items tend to be most heavily concentrated. It is generally the value of the variable which appears to occur most frequently in the distribution.

1. Mode for a Raw Data

Mode from the following numbers of a variable 70, 80, 90, 96, 70, 96, 96, 90 is 96 as 96 occurs maximum number of times.

2 For Classified Distribution

The class having the maximum frequency is called the modal class and the middle point of the modal class is called the crude mode.

The class just before the modal class is called pre-modal class and the class after the modal class is called the post-modal class.

Mode for Classified Data (Continuous Distribution)

$$M_0 = l + (f_0 - f_1 / 2 f_0 - f_1 - f_2) \times h$$

Where, l = lower limit of the modal class

f_0 = frequency of the modal class

f_1 = frequency of the pre-modal class

f_2 = frequency of the post-modal class

h = length of the class interval

Relation between Mean, Median and Mode

(i) Mean — Mode = 3 (Mean — Median)

(ii) Mode = 3 Median — 2 Mean

Symmetrical and Skew distribution

A distribution is symmetric, if the same number of frequencies is found to be distributed at the same linear distance on either side of the mode. The frequency curve is bell shaped and $A = M_d = M_0$

In anti-symmetric or skew distribution, the variation does not have symmetry.

(i) If the frequencies increase sharply at beginning and decrease slowly after modal value, then it is called positive skewness and $A > M_d > M_0$.

(ii) If the frequencies increases slowly and decreases sharply after modal value, the skewness is said to be negative and $A < M_d < M_o$.

Measure of Dispersion

The degree to which numerical data tend to spread about an average value is called the dispersion of the data. The four measure of dispersion are

1. Range
2. Mean deviation
3. Standard deviation
4. Square Deviation

Range

The difference between the highest and the lowest element of a data called its range.

$$\text{i.e., Range} = X_{\max} - X_{\min}$$

$$\therefore \text{The coefficient of range} = \frac{X_{\max} - X_{\min}}{X_{\max} + X_{\min}}$$

It is widely used in statistical series relating to quality control in production.

$$\text{(i) Inter quartile range} = Q_3 - Q_1$$

(ii) Semi-inter quartile range (Quartile deviation)

$$\therefore QD = \frac{Q_3 - Q_1}{2}$$

$$\text{and coefficient of quartile deviation} = \frac{Q_3 - Q_1}{Q_3 + Q_1}$$

$$\text{(iii) } QD = \frac{2}{3} SD$$

Mean Deviation (MD)

The arithmetic mean of the absolute deviations of the values of the variable from a measure of their Average (mean, median, mode) is called Mean Deviation (MD). It is denoted by δ .

(i) For simple (discrete) distribution

$$\delta = \Sigma |x - z| / n$$

where, n = number of terms, z = A or M_d or M_o

(ii) For unclassified frequency distribution

$$\delta = \Sigma f |x - z| / \Sigma f$$

(iii) For classified distribution

$$\delta = \Sigma f |x - z| / \Sigma f$$

Here, x is for class mark of the interval.

(iv) MD = 4 / 5 SD

(v) Average (Mean or Median or Mode) = Mean deviation from the average / Average

Note The mean deviation is the least when measured from the median.

Coefficient of Mean Deviation

It is the ratio of MD and the mean from which the deviation is measured. Thus, the coefficient of MD

$$= \delta A / A \text{ or } \delta M_d / M_d \text{ or } \delta M_o / M_o$$

Standard Deviation (σ)

Standard deviation is the square root of the arithmetic mean of the squares of deviations of the terms from their AM and it is denoted by σ .

The square of standard deviation is called the **variance** and it is denoted by the symbol σ^2 .

(i) For simple (discrete) distribution

$$\sigma = \sqrt{\frac{\Sigma (x - \bar{x})^2}{n}} = \sqrt{\frac{\Sigma d^2}{n}}$$

(ii) For frequency distribution

$$\sigma = \sqrt{\frac{\sum f(x - \bar{x})^2}{\sum f}} = \sqrt{\frac{\sum fd^2}{\sum f}}$$

(iii) For classified data

$$\sigma = \sqrt{\frac{\sum f(x - \bar{x})^2}{\sum f}} = \sqrt{\frac{\sum fd^2}{\sum f}}$$

Here, x is class mark of the interval.

Shortcut Method for SD $\sigma = \sqrt{\frac{\sum fd^2}{\sum f} - \left(\frac{\sum fd}{\sum f}\right)^2}$

where, $d = x - A'$ and $A' =$ assumed mean

Standard Deviation of the Combined Series

If n_1, n_2 are the sizes, X_1, X_2 are the means and σ_1, σ_2 are the standard deviation of the series, then the standard deviation of the combined series is

$$\sigma = \sqrt{\frac{n_1(\sigma_1^2 + d_1^2) + n_2(\sigma_2^2 + d_2^2)}{n_1 + n_2}}$$

where, $d_1 = \bar{X}_1 - \bar{X}, d_2 = \bar{X}_2 - \bar{X}$

Effects of Average and Dispersion on Change of origin and Scale

	Change of origin	Change of scale
Mean	Dependent	Dependent
Median	Not dependent	Dependent
Mode	Not dependent	Dependent
Standard Deviation	Not dependent	Dependent
Variance	Not dependent	Dependent

Important Points to be Remembered

- (i) The ratio of SD (σ) and the AM (x) is called the coefficient of standard deviation (σ / x).
- (ii) The percentage form of coefficient of SD i.e., $(\sigma / x) * 100$ is called coefficient of variation.
- (iii) The distribution for which the coefficient of variation is less is called more consistent.

(iv) Standard deviation of first n natural numbers is $\sqrt{n^2 - 1} / 12$

(v) Standard deviation is independent of change of origin, but it is depend on change of scale.

Root Mean Square Deviation (RMS)

The square root of the AM of squares of the deviations from an assumed mean is called the root mean square deviation. Thus,

(i) For simple (discrete) distribution

$$S = \sqrt{\Sigma (x - A')^2 / n}, \quad A' = \text{assumed mean}$$

(ii) For frequency distribution

$$S = \sqrt{\Sigma f (x - A')^2 / \Sigma f}$$

if $A' = A$ (mean), then $S = \sigma$

Important Points to be Remembered

(i) The RMS deviation is the least when measured from AM.

(ii) The sum of the squares of the deviation of the values of the variables is the least when measured from AM.

$$(iii) \sigma^2 + A^2 = \Sigma fx^2 / \Sigma f$$

(iv) For discrete distribution $f=1$, thus $\sigma^2 + A^2 = \Sigma x^2 / n$.

(v) The mean deviation about the mean is less than or equal to the SD. i.e., $MD \leq \sigma$

Correlation

The tendency of simultaneous variation between two variables is called correlation or covariance. It denotes the degree of inter-dependence between variables.

1. Perfect Correlation

If the two variables vary in such a manner that their ratio is always constant, then the correlation is said to be perfect.

2. Positive or Direct Correlation

If an increase or decrease in one variable corresponds to an increase or decrease in the other, then the correlation is said to the negative.

3. Negative or Indirect Correlation

If an increase or decrease in one variable corresponds to a decrease or increase in the other, then correlation is said to be negative.

Covariance

Let (x_i, y_i) , $i = 1, 2, 3, \dots, n$ be a bivariate distribution where x_1, x_2, \dots, x_n are the values of variable x and y_1, y_2, \dots, y_n those as y , then the cov (x, y) is given by

$$(i) \text{ cov}(x, y) = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})$$

where, \bar{x} and \bar{y} are mean of variables x and y .

$$(ii) \text{ cov}(x, y) = \frac{1}{n} \sum_{i=1}^n x_i y_i - \left(\frac{1}{n} \sum_{i=1}^n x_i \right) \left(\frac{1}{n} \sum_{i=1}^n y_i \right)$$

Karl Pearson's Coefficient of Correlation

The correlation coefficient $r(x, y)$ between the variable x and y is given

$$r(x, y) = \text{cov}(x, y) / \sqrt{\text{var}(x) \text{var}(y)} \text{ or } \text{cov}(x, y) / \sigma_x \sigma_y$$

$$= \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2} \sqrt{\sum_{i=1}^n (y_i - \bar{y})^2}}$$

If (x_i, y_i) , $i = 1, 2, \dots, n$ is the bivariate distribution, then

$$\text{cov}(x, y) = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y}), -1 \leq r(x, y) \leq 1$$

Properties of Correlation

$$(i) -1 \leq r \leq 1$$

(ii) If $r = 1$, the coefficient of correlation is perfectly positive.

(iii) If $r = -1$, the correlation is perfectly negative.

- (iv) The coefficient of correlation is independent of the change in origin and scale.
- (v) If $-1 < r < 1$, it indicates the degree of linear relationship between x and y , whereas its sign tells about the direction of relationship.
- (vi) If x and y are two independent variables, $r = 0$
- (vii) If $r = 0$, x and y are said to be uncorrelated. It does not imply that the two variates are independent.
- (viii) If x and y are random variables and a, b, c and d are any numbers such that $a \neq 0, c \neq 0$, then

$$r(ax + b, cy + d) = |ac| / ac r(x, y)$$

(ix) **Rank Correlation** (Spearman's) Let d be the difference between paired ranks and n be the number of items ranked. The coefficient of rank correlation is given by

$$\rho = 1 - \frac{\sum d^2}{n(n^2 - 1)}$$

- (a) The rank correlation coefficient lies between -1 and 1 .
- (b) If two variables are correlated, then points in the scatter diagram generally cluster around a curve which we call the curve of regression.
- (x) **Probable Error and Standard Error** If r is the correlation coefficient in a sample of n pairs of observations, then its standard error is given by

$$1 - r^2 / \sqrt{n}$$

And the probable error of correlation coefficient is given by $(0.6745) (1 - r^2 / \sqrt{n})$.

Regression

The term regression means stepping back towards the average.

Lines of Regression

The line of regression is the line which gives the best estimate to the value of one variable for any specific value of the other variable. Therefore, the line of regression is the line of best fit and is obtained by the principle of least squares.

Regression Analysis

- (i) Line of regression of y on x ,

$$y - \bar{y} = r \sigma_y / \sigma_x (x - \bar{x})$$

(ii) Line of regression of x and y,

$$x - \bar{x} = r \sigma_x / \sigma_y (y - \bar{y})$$

(iii) Regression coefficient of y on x and x on y is denoted by

$$b_{yx} = r \sigma_y / \sigma_x, b_{yx} = \text{cov}(x, y) / \sigma_x^2 \text{ and } b_{xy} = r \sigma_x / \sigma_y, b_{xy} = \text{cov}(x, y) / \sigma_y^2$$

(iv) Angle between two regression lines is given by

$$\theta = \tan^{-1} \left\{ \left(\frac{1 - r^2}{r} \right) \left(\frac{\sigma_x \sigma_y}{\sigma_x^2 + \sigma_y^2} \right) \right\}$$

(a) If $r = 0$, $\theta = \pi / 2$, i.e., two regression lines are perpendicular to each other.

(b) If $r = 1$ or -1 , $\theta = 0$, so the regression lines coincide.

Properties of the Regression Coefficients

(i) Both regression coefficients and r have the same sign.

(ii) Coefficient of correlation is the geometric mean between the regression coefficients.

(iii) $0 < |b_{xy} b_{yx}| \leq 1$, if $r \neq 0$

i.e., if $|b_{xy}| > 1$, then $|b_{yx}| < 1$

(iv) Regression coefficients are independent of the change of origin but not of scale.

(v) If two regression coefficient have different sign, then $r = 0$.

(vi) Arithmetic mean of the regression coefficients is greater than the correlation coefficient.
